This is a collection of problems we've done and found particularly cute/beautiful/hard, inspired by chapter 11 of *Euclidean Geometry in Math Olympiads* and Eric Shen's paper *Geometry At Its Best*. Have fun! (Note: Here, ∞_{XY} denotes the point at infinity along line XY.)

♣ O Problems

Remark. Some attempt has been made to deviate from the aformentioned two famous geometry papers.

:)))

Problem 1 (SL 1998/G4). Let M and N be two points inside triangle ABC such that

$$\angle MAB = \angle NAC$$
 and $\angle MBA = \angle NBC$.

Prove that

$$\frac{AM \cdot AN}{AB \cdot AC} + \frac{BM \cdot BN}{BA \cdot BC} + \frac{CM \cdot CN}{CA \cdot CB} = 1.$$

Problem 2 (SL 2009/G3). Let ABC be a triangle. The incircle of ABC touches the sides AB and AC at the points Z and Y, respectively. Let G be the point where the lines BY and CZ meet, and let R and S be points such that the two quadrilaterals BCYR and BCSZ are parallelogram. Prove that GR = GS.

Problem 3 (SL 2015/G4). Let ABC be an acute triangle and let M be the midpoint of AC. A circle ω passing through B and M meets the sides AB and BC at points P and Q respectively. Let T be the point such that BPTQ is a parallelogram. Suppose that T lies on the circumcircle of ABC. Determine all possible values of $\frac{BT}{RM}$.

Problem 4 (SL 2016/G7). Let I be the incentre of a non-equilateral triangle ABC, I_A be the A-excentre, I'_A be the reflection of I_A in BC, and I_A be the reflection of line AI'_A in AI. Define points I_B , I'_B and line I_B analogously. Let P be the intersection point of I_A and I_B .

- (a) Prove that *P* lies on line *OI* where *O* is the circumcentre of triangle *ABC*.
- (b) Let one of the tangents from P to the incircle of triangle ABC meet the circumcircle at points X and Y. Show that $\angle XIY = 120^{\circ}$.

Problem 5 (EGMO 2015/6). Let H be the orthocentre and G be the centroid of acute-angled triangle ABC with $AB \neq AC$. The line AG intersects the circumcircle of ABC at A and P. Let P' be the reflection of P in the line BC. Prove that $\angle CAB = 60$ if and only if HG = GP'.

Problem 6 (Iran TST 2018/1/4). Let ABC be a triangle ($\angle A \neq 90^{\circ}$), with altitudes \overline{BE} , \overline{CF} . The bisector of $\angle A$ intersects \overline{EF} , \overline{BC} at M, N. Let P be a point such that $\overline{MP} \perp \overline{EF}$ and $\overline{NP} \perp \overline{BC}$. Prove that \overline{AP} bisects \overline{BC} .

Problem 7 (Eric Shen). In $\triangle ABC$, let D, E, F be the feet of the altitudes from A, B, C respectively, and let O be the circumcenter. Points X, Y are the projections of E, F onto \overline{AD} respectively. Let $Z = \overline{AO} \cap \overline{EF}$. There exists a point T such that $\angle DTZ = 90^\circ$ and AZ = AT. If $P = \overline{AD} \cap \overline{TZ}$, and Q lies on \overline{EF} such that $\overline{PQ} \parallel \overline{BC}$, prove that \overline{AQ} is a median.

Problem 8 (China TST 2015/2/3). Let $\triangle ABC$ be an acute triangle with circumcenter O and centroid G. Let D be the midpoint of \overline{BC} , and E be on (BC) with $\overline{AE} \perp \overline{BC}$. Let $F = \overline{EG} \cap \overline{AD}$. Define points $K, L \in \overline{BC}, M \in \overline{AB}, N \in \overline{AC}$ with $\overline{FK} \parallel \overline{OB}, \overline{FL} \parallel \overline{OC}$, and $\overline{MK}, \overline{NL} \perp \overline{BC}$.

Let ω be the circle tangent to \overline{OB} , \overline{OC} at B, C respectively. Prove that (AMN) is tangent to ω .

Problem 9 (IMO 2019/6). Let *I* be the incenter of acute triangle *ABC* with $AB \neq AC$. The incircle ω of *ABC*

is tangent to sides BC, CA, and AB at D, E, and F, respectively. The line through D perpendicular to EF meets ω at R. Line AR meets ω again at P. The circumcircles of triangle PCE and PBF meet again at Q.

Prove that lines DI and PQ meet on the line through A perpendicular to AI.

Problem 10 (MOP 2019 & USA TST 2019/6). Let ABC be a triangle with incenter I, and let D be a point on line BC satisfying $\angle AID = 90^{\circ}$. Let the excircle of triangle ABC opposite the vertex A be tangent to \overline{BC} at A_1 . Define points B_1 on \overline{CA} and C_1 on \overline{AB} analogously, using the excircles opposite B and C, respectively.

- (a) (MOP 2019) Let E, F be the feet of the altitudes from B, C respectively. Prove that if \overline{EF} touches the incircle, then quadrilateral $AB_1A_1C_1$ is cyclic.
- (b) (USA TST 2019/6) Prove that if quadrilateral $AB_1A_1C_1$ is cyclic, then \overline{AD} is tangent to the circumcircle of $\triangle DB_1C_1$.

Problem 11 (TSTST 2018/3). Let ABC be an acute triangle with incenter I, circumcenter O, and circumcircle Γ . Let M be the midpoint of \overline{AB} . Ray AI meets \overline{BC} at D. Denote by ω and γ the circumcircles of $\triangle BIC$ and $\triangle BAD$, respectively. Line MO meets ω at X and Y, while line CO meets ω at C and C. Assume that C lies inside C0 and C1 and C2 and C3.

Consider the tangents to ω at X and Y and the tangents to γ at A and D. Given that $\angle BAC \neq 60^{\circ}$, prove that these four lines are concurrent on Γ .

Problem 12 (IMO 2021/3). Let D be an interior point of the acute triangle ABC with AB > AC so that $\angle DAB = \angle CAD$. The point E on the segment AC satisfies $\angle ADE = \angle BCD$, the point E on the segment E satisfies E satisfies E and E satisfies E satisfies E satisfies E and E satisfies E satisfies

Problem 13 (RMM 2012/6 & Brazil 2013/6). In triangle *ABC* with incenter *I* and circumcenter *O*, let the incircle ω touch \overline{BC} , \overline{CA} , \overline{AB} at *D*, *E*, *F* respectively.

- (RMM 2012/6) Let ω_a be the circle through B and C tangent to ω , and define ω_b , ω_c similarly. Finally, let $A' = \omega_b \cap \omega_c \ (\neq A)$, and similarly for points B' and C'.
- (Brazil 2013/6) Let P be the Gergonne point of $\triangle ABC$, and its reflections in \overline{EF} , \overline{FD} and \overline{DE} be P_a , P_b , P_c , respectively.

Prove that $P_a \in \overline{AA'}$, and that $\overline{AP_aA'}$, $\overline{BP_bB'}$, $\overline{CP_cC'}$, \overline{IO} are concurrent.

Problem 14 (USAMO 2021/6). Let ABCDEF be a convex hexagon satisfying $\overline{AB} \parallel \overline{DE}, \overline{BC} \parallel \overline{EF}, \overline{CD} \parallel \overline{FA}$, and

$$AB \cdot DE = BC \cdot EF = CD \cdot FA$$
.

Let X, Y, and Z be the midpoints of \overline{AD} , \overline{BE} , and \overline{CF} . Prove that the circumcenter of $\triangle ACE$, the circumcenter of $\triangle BDF$, and the orthocenter of $\triangle XYZ$ are collinear.

Problem 15 (SL 2021/G8). Let ABC be a triangle with circumcircle ω and let Ω_A be the A-excircle. Let X and Y be the intersection points of ω and Ω_A . Let P and Q be the projections of A onto the tangent lines to Ω_A at X and Y respectively. The tangent line at P to the circumcircle of the triangle APX intersects the tangent line at Q to the circumcircle of the triangle AQY at a point R. Prove that $\overline{AR} \perp \overline{BC}$.

♣1 Solutions

♣ 1.1 SL 1998/G4

Let M and N be two points inside triangle ABC such that

$$\angle MAB = \angle NAC$$
 and $\angle MBA = \angle NBC$.

Prove that

$$\frac{AM \cdot AN}{AB \cdot AC} + \frac{BM \cdot BN}{BA \cdot BC} + \frac{CM \cdot CN}{CA \cdot CB} = 1.$$

♣ 1.2 SL 2015/G4

Let ABC be an acute triangle and let M be the midpoint of AC. A circle ω passing through B and M meets the sides AB and BC at points P and Q respectively. Let T be the point such that BPTQ is a parallelogram. Suppose that T lies on the circumcircle of ABC. Determine all possible values of $\frac{BT}{BM}$.

Solution by CyclicISLscelesTrapezoid.

The answer is $\sqrt{2}$ only. Let the $X \neq B$ be defined as $(ABC) \cap (BPMQ)$, and let N be the midpoint of \overline{BT} .

Claim 1 - *XNMT* is cyclic.

Proof. Since N is also the midpoint of \overline{PQ} , there is a spiral similarity at X sending PNQ to AMC. Thus, we have

$$\angle XMN = \angle XAP = \angle XTB$$
,

so XNMT is cyclic.

Claim 2 – \overline{BM} is tangent to the circumcircle of XNMT.

Proof. We have

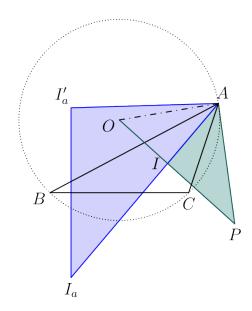

$$\angle XNM = \angle XPA = \angle XPB = \angle XMB$$
.

By Power of a Point, $BM^2 = BN \cdot BT = \frac{BT^2}{2}$, so $\frac{BT}{BM} = \sqrt{2}$.

♣ 1.3 SL 2016/G7

Let I be the incentre of a non-equilateral triangle ABC, I_A be the A-excentre, I'_A be the reflection of I_A in BC, and I_A be the reflection of line AI'_A in AI. Define points I_B , I'_B and line I_B analogously. Let P be the intersection point of I_A and I_B .

- (a) Prove that *P* lies on line *OI* where *O* is the circumcentre of triangle *ABC*.
- (b) Let one of the tangents from P to the incircle of triangle ABC meet the circumcircle at points X and Y. Show that $\angle XIY = 120^{\circ}$.

Redefine P as the inverse of I; it's clear via Poncelet spam that this point satisfies the second part. For the first part we assert more strongly that:

Claim -
$$\triangle AI_aI'_a \stackrel{+}{\sim} \triangle API$$
.

Proof. One of the few uses of SAS similarity? By angle chasing, $\angle I_a = \angle P$ follows easily. To finish, we show $I_aI'_a/I_aA = IP/AP$; indeed, the first ratio equals $2\cos\angle BI_aC = 2\sin\frac{A}{2}$ because of similar triangles; thus, we're left to length chase IP/AP; this becomes

$$\frac{OP}{AP} - \frac{OI}{OA}\frac{OA}{AP} = \frac{OI}{AI} - \frac{OI^2}{OA \cdot AI} = \frac{R}{AI} - \frac{R^2 - 2rR}{R \cdot AI}$$
$$= \frac{R - (R - 2r)}{AI} = 2\sin\frac{A}{2},$$

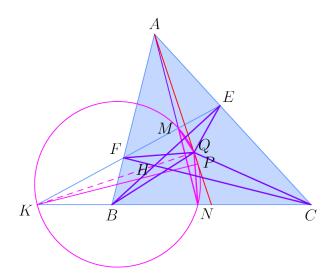

so the ratios are equal, as needed.

The claim clearly implies the isogonality.

Remark. Surprising how people found the inverse but not the similar triangles...

♣ 1.4 Iran TST 2018/1/4, by Iman Maghsoudi & Hooman Fattahi

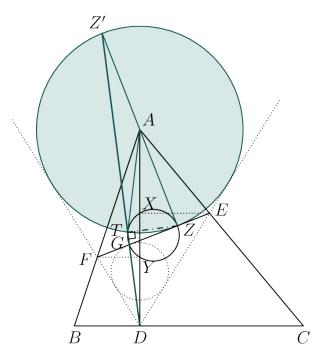

Let ABC be a triangle $(\angle A \neq 90^\circ)$, with altitudes \overline{BE} , \overline{CF} . The bisector of $\angle A$ intersects \overline{EF} , \overline{BC} at M, N. Let P be a point such that $\overline{MP} \perp \overline{EF}$ and $\overline{NP} \perp \overline{BC}$. Prove that \overline{AP} bisects \overline{BC} .

lol

♣ 1.5 Mock AIME 2019/15', by Eric Shen & Raymond Feng

In $\triangle ABC$, let D, E, F be the feet of the altitudes from A, B, C respectively, and let O be the circumcenter. There exists a point T such that $\triangle DTZ = 90^\circ$ and AZ = AT. If $P = \overline{AZ} \cap \overline{QT}$, and Q lies on \overline{EF} such that $\overline{PQ} \parallel \overline{BC}$, prove that \overline{AQ} bisects \overline{BC} .

Construct points X, Y as the projections of E, F onto \overline{AD} respectively. *

After drawing a diagram on Geogebra, we obtain:

Characterization of T

T is the harmonic conjugate of Z wrt XY – i.e. it lies on $\omega = (XYZ)$ so that the resulting quadrilateral is harmonic.

In American style, we show that this choice of T lies on ω_a (defined as the circle at A thru Z) and (DZ),

Verification (inspired by USA TST 2015/1)

For AZ = AT, we use power of a point / length chase to get $AZ^2 = AX \cdot AY$ whence \overline{AZ} touches ω . Hence, by harmonics \overline{AT} is also tangent to ω , so this property follows.

 $\angle DTZ = 90^{\circ}$ is much less straightforward. We define Z' = 2A - Z and G = E + F - Z as the antipodes of Z on the circle at A through Z. By a well-known lemma, D, Z', G collinear (along the cevian through the intouch point in $\triangle DEF$).

But also at the same time, T is on ω , $\omega_a \Rightarrow \angle ZTG = \angle ZTZ' = \pi/2$ due to antipodes. Hence, $\angle DTZ = \pi/2$, completing the verification.

^{*}Eric Shen originally included these points in the problem statement (as seen in the 2019 version of "Geometry At Its Best"), but I guess the problem's made harder by deleting them. For me, thinking about their relevance/use was important in making nonzero progress on the problem.

By this definition, we clearly have (AP; XY) = -1. From here (the chase is best discovered backwards), harmonic chasing suffices. Define $K = \overline{EF} \cap \overline{A} \otimes_{BC}$. Then

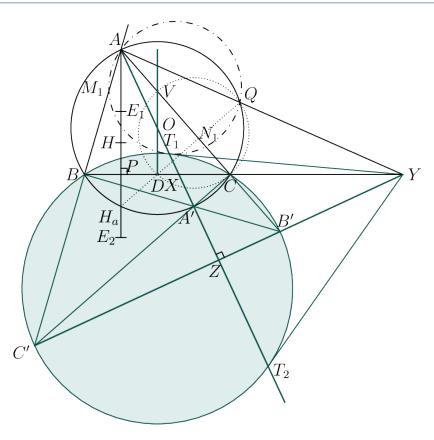

$$(\overline{AQ} \cap \overline{BC}, \infty_{BC}; B, C) \stackrel{A}{=} (QK; FE) \stackrel{\infty_{BC}}{=} (PA; YX) = -1,$$

the end!

♣ 1.6 China TST 2015/2/3

Let $\triangle ABC$ be an acute triangle with circumcenter O and centroid G. Let D be the midpoint of \overline{BC} , and E be on (BC) with $\overline{AE} \perp \overline{BC}$. Let $F = \overline{EG} \cap \overline{AD}$. Define points $K, L \in \overline{BC}, M \in \overline{AB}, N \in \overline{AC}$ with $\overline{FK} \parallel \overline{OB}, \overline{FL} \parallel \overline{OC}$, and $\overline{MK}, \overline{NL} \perp \overline{BC}$.

Let ω be the circle tangent to \overline{OB} , \overline{OC} at B, C respectively. Prove that (AMN) is tangent to ω .

As much of the parallel/perpendicular lines aren't even relevant (just to give us some equal ratios), we simplify as follows:

Problem reworded

In acute $\triangle ABC$ with circumcenter O and orthocenter H, D is the midpoint of \overline{BC} , and the altitude from A meets (BC) at E (either one works). Let U, $V = \overline{OD} \cap \overline{AB}$, \overline{AC} , respectively; define M, $N \in \overline{AB}$, \overline{AC} with (lengths directed)

$$UM/MB = VN/NC = AE/EH$$
.

Let ω be the circle tangent to segments OB, OC at B, C respectively. Prove that (AMN) is tangent to ω .

We define a load of new points as follows.

- A' = 2O A;
- E_1 , E_2 be the choices of E with AE/EH > 0 and AE/EH < 0 respectively. We will only consider M_1 , N_1 , because the negative case is identically handled;
- T_1 , $T_2 = \overline{AO} \cap \omega$, $X = \overline{AO} \cap \overline{BC}$, corresponding to E_1 , E_2 from earlier;

- $Y = \overline{T_1 T_1} \cap \overline{T_2 T_2} \cap \overline{BC}$ (which exists since $(BC; T_1 T_2) = -1$);
- Q as the harmonic conjugate of A' wrt BC, or equivalently, the reflection of the A-orthocenter Miquel point Q_a in the perpendicular bisector of \overline{BC} , \overline{DUV} .

Claim 1 - *Q* is the Miquel point of *ABCDUV*.

Proof. Observe that $Q \in \overline{H_aD}$, which follows by $Q_a \in \overline{A'PH}$ reflected in \overline{DUV} . The result holds by Reim because AH_aQC cyclic and $\overline{DV} \parallel \overline{AH_a}$.

Claim 2 -
$$(AQT_1)$$
 touches ω , $\overline{YT_1}$ at T_1 .

Proof. Sufficient to show $Q \in \overline{AY}$, so that the claim will follow by power of a point @Y. Indeed,

$$-1 = (BC; XY) \stackrel{A}{=} (B, C; A', \overline{AY} \cap (ABC))$$

so we're done.

Claim 3 -
$$AE_1/E_1H = AT_1/T_1A'$$
.

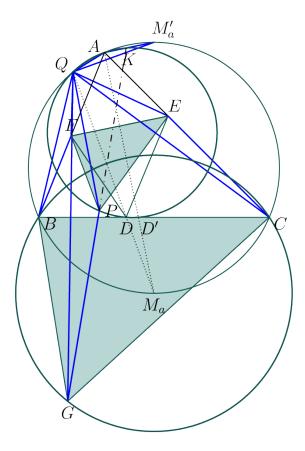

Proof. Define $B' = \overline{A'B} \cap \overline{AC}$, $C' = \overline{A'C} \cap \overline{AB}$. Using the logic of **USA TST 2007/5**, we know that $\triangle ABC \stackrel{\sim}{\sim} \triangle AB'C'$, and that Q is the A-orthocenter Miquel point in $\triangle AB'C'$. Next, let P, Z be the foot from A to $\overline{BC}, \overline{B'C'}$ respectively. If P denotes the reflection + homothety at P that maps P and P then observing that P then P then observing that P then P then P that P then P then P that P then P that P then P that P then P then P that P then P t

To finish the problem, observe M_1 , $N_1 \in (AQT_1)$ follows by spiral similarity at Q, completing the proof.

♣ 1.7 IMO 2019/6, by Anant Mudgal

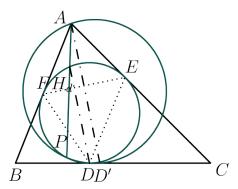

Let I be the incenter of acute triangle ABC with $AB \neq AC$. The incircle ω of ABC is tangent to sides BC, CA, and AB at D, E, and F, respectively. The line through D perpendicular to \overline{EF} meets ω at R. Line AR meets ω again at P. The circumcircles of triangle PCE and PBF meet again at Q.

Prove that lines DI and PQ meet on the line through A perpendicular to \overline{AI} .

Observe that P is the D-orthocenter Miquel in $\triangle DEF$. Define K as the intersection of the A-external bisector with \overline{AD} . We make the following definitions...

- Let ω , ω_a denote the incircle and (*BIC*) respectively;
- Define X as intersection of segment PK with ω . Let Q instead denote the A-SD point;
- G be the harmonic conjugate of I wrt BC, D' as the foot of the A-angle bisector; M_a as the midpoint of arc BC exc. A; M'_a as the antipode of M_a on (ABC);
- H as orthocenter of $\triangle DEF$, and H_d its reflection over \overline{EF} .
- \Rightarrow because $MB^2 = MD \cdot MQ = MD' \cdot MA$, $Q \in (ADD'K)$.

Claim 1 - $P \in (ADD'KQ)$.

Proof. Observe that $(PH_d; EF) = -1$ whence A, P, H_d collinear. Then because $\overline{DH_d} \parallel \overline{AI}$ because both perpendicular to \overline{EF} . Hence result by degenerate Reim.

Claim 2 - $\triangle PFE \stackrel{+}{\sim} \triangle GBC$.

Proof. Proceed by spiral at Q. Observe that $\triangle H_dEF \stackrel{+}{\sim} \triangle ICB$ by angle chase. Because $(H_dP;EF)=(IG;BC)=-1$, the needed similarity follows.

Claim 3 - *K*, *G*, *P* collinear.

Proof. An angle chase, using the previous two claims:

$$\angle QPK \stackrel{\text{claim I}}{=} \angle QAK = \angle QAM_a \stackrel{\text{spiral}}{=} \angle QPG,$$

Using last two claims, we may chase:

$$\angle PXB = \angle GXB = \angle GCB \stackrel{\text{spiral}}{=} \angle PEF = \angle PFB$$

whence PXFB (and also PXEC by symmetry) cyclic.

This completes the proof.

Remark. ggb way too op

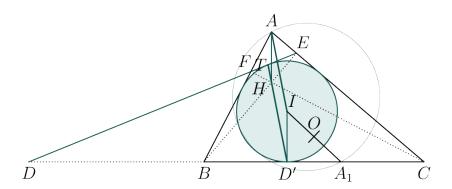

the end.

♣ 1.8 MOP + USA TST, by Ankan Bhattacharya

Let ABC be a triangle with incenter I, and let D be a point on line BC satisfying $\angle AID = 90^{\circ}$. Let the excircle of triangle ABC opposite the vertex A be tangent to \overline{BC} at A_1 . Define points B_1 on \overline{CA} and C_1 on \overline{AB} analogously, using the excircles opposite B and C, respectively.

♣1.8.1 MOP

Let E, F be the feet of the altitudes from B, C respectively. Prove that if \overline{EF} touches the incircle, then quadrilateral $AB_1A_1C_1$ is cyclic.

Call the incircle ω .

Claim 1 – D, E, F are collinear.

Proof. We will prove that the tangent line from D is antiparallel to \overline{BC} wrt $\angle A$. Indeed, this line is found by reflecting \overline{DBC} over \overline{DI} , a line perpendicular to \overline{AI} , so we win.

Let ω touch \overline{DEF} at a point T, and let D' denote the A-intouch point.

Claim 2 - $\overline{AI} \parallel \overline{HD'}$; hence AID'H is a parallelogram and AH = r, the inradius of $\triangle ABC$.

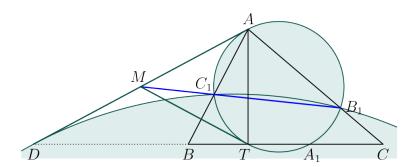

Proof. Because *BCEF* is tangential, it follows by degenerate Brianchon that lines *BE, CF, DT'* concur, i.e. $H \in \overline{TD'}$. Observe that DT = DD'; then $\overline{THD'} \perp \overline{DI}$ by symmetry, while $\overline{AI} \perp \overline{DI}$ is given; the lines are thus parallel as claimed.

Now, let ω_a , etc denote (AB_1C_1) , etc, respectively. We observe that because the perpendicular from A_1 to \overline{BC} and its cyclic variants all concur at the point 2O-I, it follows that all three circles must concur at this point by Miquel spam.

But because r/2 = AH/2 is the distance from O to \overline{BC} , we actually have $2O - I = A_1$ (also because of their feet onto \overline{BC}). Hence $A_1 \in \omega_a$ as desired.

\$1.8.2 USA TST 2019/6

Prove that if quadrilateral $AB_1A_1C_1$ is cyclic, then \overline{AD} is tangent to the circumcircle of $\triangle DB_1C_1$.

We first make some observations from working backwards on the previous part.

First, $\overline{I_aA_1}$ is unconditionally the raxis of ω_b , ω_c , which is because 2O - I, A_1 , I_a lie on the same line $\bot \overline{BC}$. Thus, if A_1 is to lie on ω_a , then by anglechase, ω_b , ω_c touch at A_1 whence $I_aA_1 \bot \overline{BC}$.

Also, by MOP 2019 converse (which follows by uniqueness wrt $\angle A$) we have D, E, F collinear. If T is the foot of A onto \overline{BC} , it follows that (DT;BC)=-1.

Claim 1 – The *A-SD* point coincides with the *A-* orthocenter Miquel.

Proof. Since
$$BF/CE = \cos B/\cos C = (s-c)/(s-b)$$
 from 19MOP, result follows by spiral.

Next, we have A, A_1 antipodes on ω_a , which follows by angle chasing, observing that ω_b , ω_c touch at A_1 / etc..

Claim 2 -
$$\overline{AD}$$
 is tangent to ω_a .

Proof. Recall that \overline{ADQ} is perpendicular to $\overline{HIQ'}$; thus, equivalent to show $\overline{HQ} \parallel \overline{AA'}$ which is another angle chase.

By radical axis/etc, it suffices to show that the midpoint M of \overline{AD} lies on $\overline{B_1C_1}$. By symmetry, \overline{MA} , \overline{TA} touch ω_a .

Claim 3 -
$$(AT; B_1C_1) = -1$$
.

Proof. Harmonics:
$$(AT; B_1C_1) \stackrel{A}{=} (DT; BC) = -1$$
, as claimed.

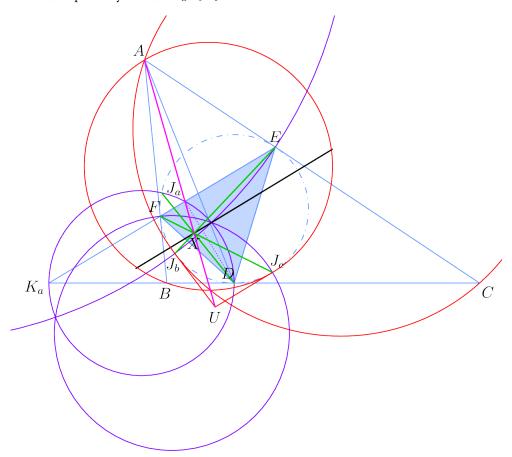

From here the problem follows by power of a point converse on $MD^2 = MA^2 = MB_1 \cdot MC_1$.

♣ 1.9 RMM + Brazil

♣ 1.9.1 RMM 2012/6

Let ABC be a triangle and let I and O denote its incentre and circumcentre respectively. Let ω_A be the circle through B and C which is tangent to the incircle of the triangle ABC; the circles ω_B and ω_C are defined similarly. The circles ω_B and ω_C meet at a point A' distinct from A; the points B' and C' are defined similarly. Prove that the lines AA', BB' and CC' are concurrent at a point on the line IO.

Let $K_a = \overline{EF} \cap \overline{BC}$, $\gamma_a = (K_aD)$, $J_a = \omega_a \cap \gamma_a \cap \omega$ (and cyclic variants), and H and ℓ denote the orthocenter and Euler line of $\triangle DEF$, respectively. Also, let I_a , I_b , I_c be the excenters of $\triangle ABC$

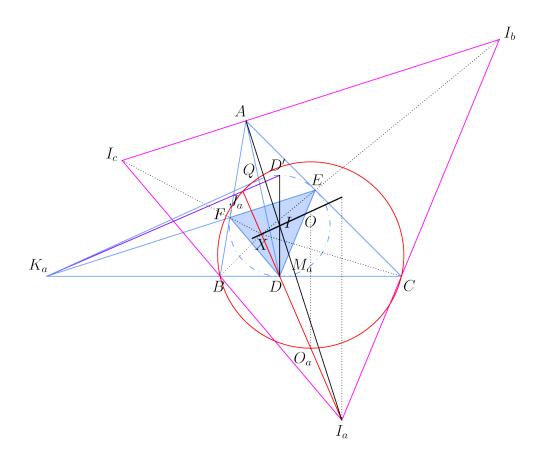

Solution 1, by radical axes Observe that ℓ is just \overline{OI} , and that γ_a , etc are coaxial Apollonian circles. Define X as the radical center of γ_a , γ_b , γ_c , ω (which exists since the former 3 circles are coaxial). We'll show this is the desired concurrency point in both problems. Clearly, $\overline{DJ_a}$ is the raxis of (γ_a, ω) , i.e. $X \in \overline{DJ_a}$.

Lemma 1 – ℓ is the raxis of γ_a and variants.

Proof. Let T_a denote the foot of D onto \overline{EF} , which is obviously on γ_a . Then H has power $HD \cdot HT_a$ (= variants) wrt the γ 's, hence on raxis; Meanwhile I has power r^2 wrt all circles by orthogonality, hence also on raxis, done. \Box

Let tangents to ω at J_b , J_c meet at U; then, \overline{AU} is the raxis of ω_b , ω_c . Clearly this is the polar of $\overline{J_bJ_c} \cap \overline{EF}$. Recalling that $X = \overline{EJ_b} \cap \overline{FJ_c}$, follows by Brokard that $X \in \overline{AU}$, the end.

Solution 2, by homothety (v4913) Let D' be the antipode of D on ω , $Q = \overline{AD} \cap \omega$ ($\neq D$); then, because (EF; DQ) = -1, $\overline{K_aQ}$ touches ω as well. Also, because $\angle DJ_aD' = \angle DJ_aK_a = 90^\circ$, K_a , J_a , D' are collinear, whence $(DQ; J_aD') = -1$.

We start with X as the similicenter of homothetic triangles DEF, $I_aI_bI_c$. Let homothety h at X with scale factor $r \max (D, E, F) \rightarrow (I_a, I_b, I_c)$, This must also map their circumcenters to each other, i.e. $I \stackrel{H}{\Rightarrow} 2O - I$, whence $X \in \overline{OI}$.

Also, let M_a be the midpoint of \overline{BC} , $O_a \in \overline{DJ_a}$ be the midpoint of arc BC on ω_a not containing J_a (and variants).

Lemma 2 – J_a , D, I_a collinear.

Proof. Harmonics:

$$-1 = (DQ; D'J_a) \stackrel{D}{=} (\overline{BC} \cap \overline{AI}, \overline{JaD} \cap \overline{AI}; I, A),$$

implying that $\overline{J_aD} \cap \overline{AI}$ is the *A*-excenter.

Hence, $X = \overline{DJ_a} \cap \overline{EJ_b} \cap \overline{FJ_c}$.

Claim - O_a is the midpoint of $\overline{DI_a}$.

Proof. By symmetry, M_a is the foot of O_a onto \overline{BC} , while it's well-known that 2M - D is the foot of I_a onto \overline{BC} . M obviously being the midpoint of the segment with endpoints D, 2M - D implies the claim by parallel lines. \Box

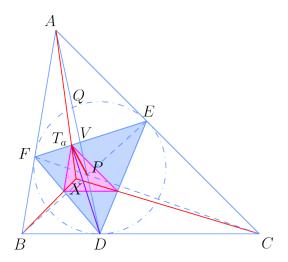

Therefore there must exist a homothety b' at X with scale factor (1+r)/2, mapping $(D, E, F) \to (O_a, O_b, O_c)$. To show that our X is indeed the radical center of ω_a , ω_b , ω_c , compute

$$\operatorname{Pow}(X, \omega_a) = XJ_a \cdot XO_a \stackrel{b'}{=} \frac{1+r}{2}XJ_a \cdot XD = \frac{\operatorname{Pow}(X, \omega)}{(r+1)/2},$$

a symmetric quantity wrt *a*, *b*, *c*.

The incircle of triangle ABC touches sides BC, CA and AB at points D, E and F, respectively. Let P be the intersection of lines AD and BE. The reflections of P with respect to EF, FD and DE are X, Y and Z, respectively. Prove that lines AX, BY and CZ are concurrent at a point on line IO, where I and O are the incenter and circumcenter of triangle ABC.

(We continue to use terminology from the previous subsubsection.) Let T_a be the projection of D onto \overline{EF} . As promised in the refactored statement in the problem section,

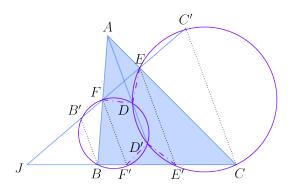

Claim - $T_a \in \overline{AXA'}$.

Proof. Because X is the similicenter of triangles DEF, $I_aI_bI_c$, it must also be similicenter of their orthic triangles. It follows that $T_a \in \overline{AX}$, as needed.

Next, let $V = \overline{AD} \cap \overline{EF}$, so that (DV; AP) = -1. Because $\angle DT_aV = 90^\circ$, \overline{EF} must bisect $\angle AT_aP$, whence $P_a \in \overline{AT_aA'}$. Considering triangles ABC, DEF, and the orthic triangle of $\triangle DEF$, the concurrency holds by cevian nest.

\$1.10 IMO 2021/3

Let D be an interior point of the acute triangle ABC with AB > AC so that $\angle DAB = \angle CAD$. The point E on the segment E satisfies E satisfies E and the point E on the segment E satisfies E sa

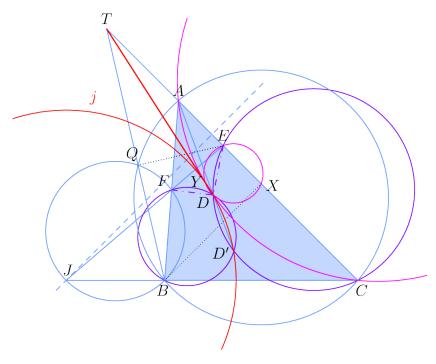

Solution by **v4913**.

Let $J = \overline{EF} \cap \overline{BC}$, and $D' \in \overline{AD}$ be the isogonal conjugate of D wrt $\triangle ABC$. The given angle conditions imply that BDD'F, CDD'E are cyclic, while power of a point at A implies BCEF cyclic as well.

Claim 1 – *J* is the exsimilicenter of (*EDC*), (*FDB*); hence, JD = JD' by symmetry.

Proof. Construct $E_1 = (CDD'E) \cap \overline{BC} \ (\neq C)$, $F_1 = (BDD'F) \cap \overline{BC} \ (\neq B)$. By isogonality, DF = D'F' and DE = D'E' whence DD'E'E, DD'F'F are both cyclic isosceles trapezoids. $\overline{DD'}$, $\overline{EE'}$, $\overline{FF'}$ share a perpendicular bisector j, and in fact, this is the bisector of $\angle J$, i.e. JE = JE', JF = JF'.

Reflect *B*, *C* over *j* to obtain *B'*, *C'*; then, because JB/JF' = JB/JF = JE/JC = JE'/JC, there is a homothety at *J* mapping $(B, B', F, F') \rightarrow (E', E, C', C)$ and thus their circumcircles $(BB'DD') \rightarrow (CC'DD')$ as well.

Let $Y = (ADC) \cap (EXD)$ ($\neq D$), Q be the Miquel point of ABCJEF, and j the circle at J through D, D'. Observing that $\overline{O_1O_2}$ is the perpendicular bisector of \overline{DY} , it remains to prove $Y \in j$.

Claim 2 - *XQEB* is cyclic.

Proof. This is a simple angle chase: using cyclic quadrilaterals (ABCQ), (JFBQ), (ECJQ), and (AEFQ), we obtain

$$\angle EQB = \angle EQA + \angle AQB = \angle ACB + \angle EFA = 2\angle ACB = \angle EXB$$

as desired.

Next, we characterize the radical axis of j, (JBF) – it's perpendicular to the line of centers and through A:

Claim 3 - The line through *B* and the center of (*JBF*) is perpendicular to \overline{AC} .

Proof. This is equivalent to " t_b , the tangent to (JBF) at J, is parallel to \overline{AC} ". Because $\angle(\overline{BJC}, t_b) = \angle BFJ = \angle JCE$, the result follows.

Because $\text{Pow}(A, j) = AD \cdot AD' = AQ \cdot AJ = \text{Pow}(A, (JBQF)), A$ is on the radical axis of j, (JBF). By the previous claim, it follows that \overline{AC} is the radical axis of j, (JBF).

To finish, define $T = \overline{DY} \cap \overline{AC} \cap \overline{BQ}$ as the radical center of (*JBF*), (*ABC*), (*EXD*), (*ADC*), and the phantom point $Y' = \overline{TD} \cap j \ (\neq D)$. Because T is on \overline{AC} , the radical axis of j, (*JBF*), we have (lengths directed)

$$TY' \cdot TD = \text{Pow}(T, j) = \text{Pow}(T, (JBF)) = \text{Pow}(T, (ABCQ)) = TA \cdot TC = TY \cdot TD \Rightarrow Y = Y',$$

the end!

\$ 1.11 SL 2021/G8

Let ABC be a triangle with circumcircle ω and let Ω_A be the A-excircle. Let X and Y be the intersection points of ω and Ω_A . Let P and Q be the projections of A onto the tangent lines to Ω_A at X and Y respectively. The tangent line at P to the circumcircle of the triangle APX intersects the tangent line at Q to the circumcircle of the triangle AQY at a point R. Prove that $\overline{AR} \perp \overline{BC}$.

Solution 1 by Brianchon from AoPS † (WIP) Redefine R as intersection of tangent at D' and A-altitude and prove PR is tangent to ω_{XPA} . Let us denote some points: $D'D' \cap AB = B', D'D' \cap AC = C', D'D' \cap XX = B', XX \cap AB = X'$ and $CX \cap AP' = M$. apply Brianchon to the polar reciprocal DD'XXB''C'':

- I. $DD \cap D'D' = \infty$
- 2. $D'D' \cap XX = P'$
- 3. $XX \cap XX = X$
- 4. $XX \cap B"B" = X'$
- 5. $B"B" \cap C"C" = A$
- 6. C"C" $\cap DD = C'$

and lines 14, 25, 36 must be concurrent. Since $AP' \cap CX = M$ we can imply that MX'|BC By angle chase $\angle MX'A = \angle P'B'A = 180 - \angle AB'C' = 180 - \angle ABC = 180 - \angle AXC = \angle MXA$ so MXX'A is concyclic. Again by angle chase $\angle MAX = \angle MX'P' = \angle X'P'B' = \angle PAR$ (since P'APR is concyclic) thus $\angle XAP = \angle P'AR = \angle P'PR$ and we are done.

Solution 2 by DDIT (CyclicISLscelesTrapezoid)
